1   **Abstract**  
2   Objective: To determine the effect size of wearing sports garments treated with microscopic  
3   titanium particles (AQUA TITAN) during recovery from strenuous running on restoration of  
4   running economy during subsequent exercise. Design: A double-blind crossover was used to  
5   determine the effect of AQUA TITAN on running metabolic cost in 10 healthy men.  
6   Participants performed 40 min of treadmill running comprising 2 x (10 min at 5% and 10 min  
7   at -10% grade), followed by random allocation to skin-tight nylon polyurethane AQUA TITAN  
8   treated or non-treated placebo garments covering the torso, limbs, and feet. Garments were  
9   worn continuously throughout the next 48-h, during which time participants rested (day 2) then  
10   completed a graded treadmill run to determine metabolic outcome (day 3). Method: Body-  
11   weight normalised running metabolic cost was evaluated by indirect calorimetry and the effect  
12   size referenced against the smallest meaningful change in economy (0.9%) for improvement  
13   in distance running performance. Results: The fatigue effect while wearing control garments  
14   on metabolic cost at 48-h was small (2.2% 95%CL  $\pm 1.2\%$ ). In contrast, AQUA TITAN  
15   garments most certainly reduced running metabolic cost (-3.1%  $\pm 0.9\%$ ) vs control.  
16   Additionally, AQUA TITAN increased the respiratory exchange ratio ( $0.011 \pm 0.005$ ) and  
17   lowered minute ventilation at intensities below the ventilator threshold (-4.0%  $\pm 0.9\%$ ).  
18   Conclusions: AQUA TITAN garments worn during recovery from strenuous exercise  
19   improved subsequent running economy to a magnitude likely to restore endurance  
20   performance. Future research should verify the magnitude of garment effects on performance  
21   outcomes, and on identifying the acute or passive neural, musculotendinous or metabolic  
22   mechanisms responsible.

23   Key words. recovery, tendon stiffness, short latency reflex, running economy, sports  
24   garments, performance

25  
26

27 **Introduction**

28 Sports garments are potential mediums for the application of compounds that may modulate  
29 the physiological response to exercise for the purpose of aiding performance and enhancing  
30 recovery. One such compound is AQUA TITAN, which results from dispersion of  
31 microtitanium particles in water<sup>1</sup>. AQUA TITAN is subsequently utilised as a dye in the  
32 manufacturing process where microtitanium particles are bonded into the fabric becoming an  
33 integral component of the garment. There is evidence to suggest that when applied close to  
34 cells or tissues, AQUA TITAN imparts physiological effects on the nervous system<sup>2,3</sup> and on  
35 muscle and tendon<sup>4-6</sup>. In humans, nylon-polyurethane AQUA TITAN-treated garments worn  
36 for 4 days following a bout of intermittent high-intensity running increased joint range of  
37 motion (ROM) and possibly lowered the metabolic cost of running, relative to non-treated  
38 placebo<sup>6</sup>. These observations are of interest because running economy is one of the strongest  
39 predictors of distance running performance<sup>7</sup>.

40

41 A number of physiological factors determine running economy, including muscle fibre  
42 characteristics, body mass, muscle-tendon elasticity and neuromuscular efficiency<sup>8</sup>. Of these  
43 factors, muscle contractility (secondary to fiber type) and tendon stiffness are thought to be  
44 important determinants of musculotendinous contributions, with the optimal tendon stiffness  
45 a component of successful specific adaptation to loading (trained optima)<sup>9</sup>. Because the rate of  
46 force development is an important determinant of tendon-muscle performance in running and  
47 jumping tasks<sup>10</sup>, altered neuromuscular firing rates could also affect contractile performance  
48 via improved neuromuscular coordination<sup>11</sup>. Therefore, improved neuromuscular coordination,  
49 attenuated reduction in tendon stiffness<sup>12</sup>, and reduced economy<sup>13</sup> after loading stress has the  
50 potential to improve skeletal muscle contractile function following strenuous exercise common  
51 to athletic training.

52

53 Building evidence suggests AQUA TITAN garments may improve musculotendinous function  
54 following strenuous running, and that this may improve muscle contractile performance and  
55 running economy. Indeed, AQUA TITAN tape applied to the triceps surae during recovery  
56 from a bout of strenuous treadmill running increased stretch-reflex response time and  
57 attenuated the fatigue-induced decline in tendon stiffness<sup>4</sup>. Therefore, we hypothesized that  
58 strenuous running would increase the metabolic cost of subsequent running (lower economy),  
59 but this effect would be attenuated with AQUA TITAN garments.

60

61    **Method**

62    Ten healthy active men participated with mean (SD) age 29.2 y (7.1), weight 78.0 kg (1.5),  
63    stature of 181.3 m (9.3), and maximum oxygen uptake ( $\text{VO}_{2\text{max}}$ ) of 65.1  $\text{mL}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$  (7.9).  
64    Inclusion criteria were aged 18 to 45 y, regular participation in a sport involving running, and  
65     $\text{VO}_{2\text{max}} > 50 \text{ mL}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$ . Exclusion criteria were history or complaints of tendinopathy or  
66    lower limb trauma, illness, or current use of analgesic medication. All participants were  
67    informed of potential risks and gave informed written consent according to the protocol  
68    approved by Massey University Research Ethics Committee.

69

70    The study design is illustrated in Figure 1. On the first visit to the laboratory, participants  
71    completed a  $\text{VO}_{2\text{max}}$  test on a calibrated motorised treadmill according to Wadsworth et al.<sup>6</sup>,  
72    with the exception of external breath-by-breath respiratory gas collection (Sensormedics  
73    Vmax, San Diago, CA). Ventilatory threshold (VT) was determined using the ventilatory  
74    equivalence method<sup>14</sup>, where VT was the treadmill running speed corresponding to the first  
75    sustained rise in the ventilatory equivalent of  $\text{O}_2$  (VE/ $\text{VO}_2$ ) without a concurrent rise in the  
76    ventilatory equivalent of  $\text{CO}_2$  (VE/ $\text{VCO}_2$ ).

77

78    The second visit 2-3 days later comprised familiarisation of the testing procedures and baseline  
79    measurement of running economy that comprised a continuous protocol of 4 min of walking  
80    at  $4 \text{ km}\cdot\text{h}^{-1}$ , 6 min running at  $9 \text{ km}\cdot\text{h}^{-1}$ , and  $5 \times 6$ -min running stages beginning  $-1.5 \text{ km}\cdot\text{h}^{-1}$  of  
81    the VT speed and increasing  $0.5 \text{ km}\cdot\text{h}^{-1}$  for each progressive stage. The protocol determined  
82    the fourth stage occurred at VT and the final stage at  $0.5 \text{ km}\cdot\text{h}^{-1}$  above VT. This protocol  
83    provided 3 estimates below the VT where steady-state  $\text{VO}_2$  is likely, and 2 at or above VT  
84    where a higher percentage of type-II muscle fibres are likely to be recruited associated lower  
85    relative oxygen economy<sup>25</sup>. The same protocol was used for the recovery running economy  
86    measurement. Body weight was measured following toileting prior to running under  
87    standardised clothing and shoe conditions. Expired gas was collected using the metabolic cart.  
88    Running economy was the metabolic cost of exercise expressed as the energy equivalent for  
89    oxygen per min adjusted for on-the-day body weight, which was determined using the final 2  
90    min data from each stage. Metabolic power ( $\text{J}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$ ) was calculated using the non-protein  
91    respiratory quotient<sup>15</sup>.

92

93    Subsequent trials involved two experimental blocks in a crossover with 7-day washout: a  
94    fatigue inducing run, rest day, and then recovery measure of running economy 48 h later

95 (Figure 1). Participants completed one experimental block wearing AQUA TITAN-treated  
96 garments and the other wearing identical placebo garments allocated by double-blind  
97 randomization. Garments were worn after the loading run, continuously during recovery,  
98 including sleeping and all exercise tests. The AQUA TITAN garments were made by Phiten  
99 Co. Ltd. (Kyoto, Japan) as described previously<sup>6</sup>. Phiten Co. Ltd had no other involvement in,  
100 nor right to approve or disapprove the current publication. The clothing was tight fitting, 81%  
101 Nylon:19% polyurethane, black, and covered the entire torso to the neck and the limbs; feet  
102 and ankles were covered with tennis length socks. To control for a potential confounding  
103 influence of different fuel substrate availability and training pre-load, participants standardised  
104 both training and diet by recording habit from 48-h prior to beginning the first block; this  
105 regimen was repeated for the second block.

106

107 On day one of the experimental block (Figure 1B) lower limb fatigue leading to reduced  
108 subsequent running economy<sup>16</sup> was induced by a 40-min treadmill run at a speed eliciting 70%  
109 VO<sub>2max</sub> during flat running. The run comprised 2 x (10 min at 5% and 10 min at -10%) modified  
110 by adding 10 min from the protocol of Braun and Dutto<sup>16</sup><sup>13</sup>. Participants reported near  
111 maximal effort on the uphill sections. Laboratory environment was 20°C, 44-50% humidity.  
112 Participants were fan cooled during running.

113

114 Sample size (n=10) was generated on the basis of sufficient power to declare a likely substantial  
115 change in running economy<sup>17</sup> drawn from the mean effect of AQUA TITAN garments on  
116 metabolic power (2.2%)<sup>6</sup> and typical error of 2.5% for metabolic power determined in our  
117 laboratory. All outcome variables were log-transformed before modelling to reduce  
118 nonuniformity of error and to express outcomes as percentages<sup>17</sup>. Outcomes were estimated  
119 with mixed linear modelling (Proc Mixed, SAS Version 9.1; SAS Institute, Cary, NC) of the  
120 breath-by-breath data comprising the interaction of trial order, treatment, and stage (fixed  
121 effects); the random effect was subject identity.

122

123 Population values of statistics were estimated by magnitude-based inference<sup>17</sup>. For reference  
124 to the primary outcome the smallest important change in metabolic cost with the likelihood of  
125 improving endurance running performance was 0.9%. This value was derived from a linear  
126 model of the physiological factors determining endurance-running performance<sup>18</sup>, where a 5%  
127 improvement in running economy corresponded to a 3.8% improvement in performance, and  
128 where a 0.7% improvement in performance was considered worthwhile<sup>6, 19</sup>. Consequently, the

denominator for calculations of effect size on metabolic cost was the threshold value divided by 0.3 corresponding to the qualifiers: trivial=0.0–0.3, small=0.3–0.9, moderate=0.9–1.6, large=1.6–2.5, very large=2.5–4.0, and extremely large >4.0<sup>17</sup>. For the other variables, the standardised difference was used (trivial=0.0–0.2, small=0.2–0.6, moderate=0.6–1.2, large=1.2–2.0, very large=2.0–4.0, and extremely large >4.0)<sup>17</sup>. The thresholds for assigning qualitative terms to probability of a substantial effect were: <0.5%, most certainly not; <5%, very unlikely; <25%, unlikely; <75%, possible; >75%, likely; >95%, very likely; >99.5%, most certain. An effect was *unclear* if the uncertainty included both substantial increases and decreases (i.e. >5%)<sup>17</sup>.

138

## 139 **Results**

140 To provide a point of reference to the loading run effect size on the subsequent metabolic cost,  
141 we determined running economy in the placebo garments at 48-h relative to that with normal  
142 untreated running clothing worn during the baseline run. Here, bodyweight normalized overall  
143 mean metabolic power very likely increased (2.2% 95%CL ±0.8%, p=5.00E-9); in contrast,  
144 the mean AQUA TITAN minus baseline reduction was likely trivial (-0.9% ±0.7%, p=0.02).  
145 Therefore, the primary outcome at 48-h was a reduction of metabolic cost with AQUA TITAN  
146 garments, relative to control (Figure 2A-B, Table 1). AQUA TITAN garments lowered minute  
147 ventilation when the running speed was below the VT (stages 1-3) by 4.0% (±0.7%, p<1.00E-  
148 18, standardized difference -0.17 ±0.03); when above the VT (stage 5), the effect was trivial  
149 (0.7% ±1.2%, p=0.34, 0.03 ±0.04) (Figure 2D). The increase in respiratory exchange ratio with  
150 AQUA TITAN was trivial (Table 1), but minute ventilation per unit O<sub>2</sub> consumption adapted  
151 to the lower oxygen cost of exercise with AQUA TITAN (Figure 2C) with a trivial decrease (-  
152 0.3 ±0.5%, p=0.36, -0.01 ±0.03).

153

## 154 **Discussion**

155 The purpose of the study was to determine the effect AQUA TITAN treated garments worn  
156 during the 48-h recovery period of recovery from a bout of strenuous running on subsequent  
157 running economy. AQUA TITAN garments lowered the metabolic cost of subsequent running  
158 by 3.1% ±6%, relative to non-treated garments. This running economy finding is consistent  
159 with a previous report<sup>6</sup>. Braun and Dutto<sup>16</sup> previously reported the mean fatigue effect of a  
160 hilly run on 48-h metabolic cost during subsequent running was 3.2%. Coupled with our  
161 estimate of the non-treated fatigue effect, these data suggest the AQUA TITAN garments  
162 enabled a restoration of running economy near to the pre-loaded condition, with the garments

163 assisting in maintenance of initial muscle contractile efficiency inferred by 166 relative  
164 restoration of the metabolic cost of subsequent exercise.

165

166 With the physiological assumption of sample equivalence between studies based on  
167 conservation of bioenergetics and  $\text{VO}_{2\text{max}}$ , Di Prampero et al.'s<sup>18</sup> linear model for bioenergetic  
168 predictors of running performance<sup>17,19</sup> provided for a prediction of the magnitude of change in  
169 distance running performance attributable to the AQUA TITAN garments. The model suggests  
170 the mean improvement in economy corresponded to a moderate 2.4% improvement in  
171 performance. Therefore, AQUA TITAN garments during recovery may be a useful  
172 intervention for athletes competing in multiple-day events where rapid recovery of muscle  
173 performance is an important component of outcome. Our study design, however, did not allow  
174 determination of whether treatment effect was derived from physiological responses that  
175 occurred while wearing AQUA TITAN during the 48-h recovery period or from acute effects  
176 during subsequent exercise, or if the leggings, socks or upper garments were responsible.

177

178 Changes to the mechanical properties of the musculotendon unit may explain the improvement  
179 in metabolic economy. Energy storage and return is thought to be optimal when the muscle  
180 contracts isometrically while the tendon lengthens<sup>20</sup>. This process works best with a compliant  
181 tendon, but if the tendon is too compliant it will impair force transmission to the bone<sup>21</sup>. For  
182 any movement, therefore, there is an optimal tendon stiffness based on the demands of the task.  
183 If we assume that running patterns have developed to produce maximal performance from the  
184 normal rested (i.e. pre-trial) tendon stiffness, any change in tendon stiffness would decrease  
185 running economy. AQUA TITAN tape<sup>4</sup> and garments<sup>6</sup> have been shown to produce small  
186 increases in joint range of motion (ROM) which could improve musculotendinous efficiency  
187 through altered gait mechanics (although we lack the data to confirm this is the case). In our  
188 companion study<sup>4</sup>, achilles tendon stiffness did not decrease following fatiguing exercise when  
189 AQUA TITAN tape was applied to the tendon. A similar effect may explain the present results.

190

191 A second possible mechanism to explain the AQUA TITAN effect is improved repair of  
192 damaged muscle tissue. It is well known that muscle damage follows strenuous eccentric  
193 exercise<sup>16,22</sup>; such tissue insult could impair stride efficiency by reducing stride length<sup>16</sup>, reduce  
194 muscle and joint ROM<sup>23</sup> and decrease knee extensor torque<sup>24</sup> thereby producing impaired  
195 contractile function and reduced running economy. Braun and Dutto<sup>16</sup> reported that reduced  
196 stride length is inversely correlated to running energy cost, suggesting damage to the preferred

197 type-I muscle fibre pool increases relative recruitment of type-II fibres. Type-II specific  
198 myosin ATPase isoforms require 1.6- to 2.1-fold more ATP per unit force production than  
199 type-I<sup>25</sup> and therefore require a proportionately higher oxidative phosphorylation. We observed  
200 4% lower minute ventilation during sub-VT exercise with AQUA TITAN. Minute ventilation  
201 is coupled to muscle contraction by locomotor muscle afferents<sup>26</sup>. Lower minute ventilation  
202 with AQUA TITAN, although possibly trivial in effect size, offers some physiological support  
203 for relatively higher relative type-I fibre recruitment profile<sup>27</sup>. Histologically, damaged muscle  
204 undergoes regeneration and repair mediated by inflammatory process associated wound  
205 healing responses followed by enhanced myogenesis<sup>28</sup>. A recent cell culture experiment  
206 suggests a possible damage repair mechanism. Ishizaki et al.<sup>5</sup> reported that AQUA TITAN  
207 coated rubber upregulated expression of myofibril components (vinculin, type I and III  
208 collagen) and accelerated myocyte and osteoblast adhesion and growth, thereby demonstrating  
209 a potential mechanism for the effect we observed.

210

211 A final perspective suggests a neural mechanism may be involved. Disrupted reflex activity of  
212 the lower limb is known to impair running gait<sup>29</sup>. Cronin et al.<sup>29</sup> reported that impaired triceps  
213 surae short latency response results in less efficient transfer of force during running. This is a  
214 significant mechanistic consideration with respect to the current study because downhill  
215 running reduces the short latency reflex response of the triceps surae<sup>30</sup>. Indeed, AQUA TITAN  
216 tape applied to the triceps surae for 48-h following high-intensity running decreased the short  
217 latency response and increased achilles tendon stiffness and ROM<sup>4</sup>; the subsequent reduced  
218 yield and stiffer tendon<sup>29</sup> could perhaps have been sufficient to improve joint efficiency during  
219 the gait cycle and therefore improve running economy. Further investigation is required to  
220 determine if improved neuromuscular coordination and recovery of tendon stiffness are the  
221 primary causal mechanisms for restoration of running economy with AQUA TITAN garments  
222 following strenuous exercise.

223

## 224 Conclusion

225 AQUA TITAN garments worn during recovery from strenuous exercise restored subsequent  
226 running economy. Current evidence for a mechanism supports improved musculotendinous  
227 contractile function via faster short latency response regulating or restoring tendon stiffness  
228 towards the pre-loaded adapted optima for running<sup>4</sup>. Further research is warranted to  
229 investigate the potential modifications of cellular repair mechanisms relating to muscle and  
230 connective tissue integrity and function during recovery, determine dose response, and

231 examine whether effects are mediated by physiological changes during the passive recovery  
232 period or during exercise. Regardless of mechanism, the magnitude and certainty of the running  
233 economy outcome implies that AQUA TITAN could have a meaningful impact on muscle  
234 contractile function during periods of intense training and in multiday competitive events.

235

### 236 **Practical implications**

- 237 • Strenuous running exercise induces fatigue and impairs running economy  
238 • Sports garments treated with uniquely-processed microtitanium particles restored  
239 running economy, which could also contribute towards restoration of running  
240 performance  
241 • Wearing AQUA TITAN treated sports apparel may benefit 247 recovery in tournament  
242 or repeated heavy training sessions

243

### 244 **Acknowledgments**

332 **Tables**

333

334 Table 1. Statistical summary of the effect of AQUA TITAN garments worn for 48-h during  
 335 recovery from strenuous hill running on the metabolic cost of movement during subsequent  
 336 running.

Outcome <sup>1</sup>	AQUA TITAN	Effect Size <sup>4</sup> minus Control	P-value	Effect	Inference <sup>4</sup>
		$\pm 95\% \text{CL}^2$		Magnitude <sup>4</sup>	
		Effect (%)			
		$\pm 95\% \text{CL}^2$			
	Normalised oxygen consumption <sup>3</sup>				
Stages 1-3	-3.9 $\pm$ 0.9	-0.9 $\pm$ 0.2	1.0E-17	Moderate	most certain
Stage 4	-1.9 $\pm$ 1.4	-0.4 $\pm$ 0.3	0.01	Small	likely
Stage 5	-2.8 $\pm$ 1.5	-0.7 $\pm$ 0.4	3.6E-04	Small	very likely
All Stages	-3.3 $\pm$ 0.6	-0.8 $\pm$ 0.2	6.0E-21	Small	most certain
	Normalized metabolic cost <sup>3</sup>				
Stages 1-3	-3.7 $\pm$ 0.9	-0.9 $\pm$ 0.2	1.0E-17	Moderate	most certain
Stage 4	-2.1 $\pm$ 1.4	-0.5 $\pm$ 0.3	0.003	Small	likely
Stage 5	-2.5 $\pm$ 1.5	-0.6 $\pm$ 0.3	8.8E-05	Small	likely
All Stages	-3.1 $\pm$ 0.6	-0.7 $\pm$ 0.2	3.0E-21	Small	most certain
	Respiratory exchange ratio <sup>3</sup>				
Stages 1-3	0.014 $\pm$ 0.004	0.12 $\pm$ 0.04	2.5E-06	Trivial	most certain
Stage 4	-0.007 $\pm$ 0.007	-0.07 $\pm$ 0.06	0.122	Trivial	most certain
Stage 5	0.020 $\pm$ 0.08	0.18 $\pm$ 0.07	8.1E-05	Trivial	possible
All Stages	0.011 $\pm$ 0.003	0.10 $\pm$ 0.03	1.5E-06	Trivial	most certain

<sup>1</sup>Stages 1-3 < ventilatory threshold (VT), stage 4 approximately VT, stage 5 > VT.

<sup>2</sup>Add or subtract this value as a factor of the mean to obtain the upper and lower confidence limits.

337

<sup>3</sup>Oxygen ( $\text{VO}_2 \cdot \text{kg}^{-1}$ ) and metabolic cost ( $\text{kJ} \cdot \text{kg}^{-1} \cdot \text{km}^{-1}$ ) data are percentage estimates, while the respiratory exchange ratio are raw unit estimates.

<sup>4</sup>Magnitude-based inferences about the true value for outcomes were qualified using the within-subject effect size for measures of running metabolic cost, where 1.3% was the threshold for smallest worthwhile change in economy with reference to endurance running performance<sup>18</sup>. See Methods for further detail.
